CH 2 - GDP and its Components

Luke Lu • 2026-10-19

2.1 GDP Definition

📘 **Definition — GDP**

GDP is the **market value** of all **final goods and services** produced within a country during a given period

$$\text{GDP} = \sum_i P_i Q_i$$

- It measures a **flow**: production over a month, quarter, or year
- It measures **economic activity**, not the **stock** of national wealth
- It is measured to support comparisons acorss time and across economies.

Market Value: output is recorded using market prices.

Final Output: Intermediate goods are not counted

Domestic production: production counts where it occurs, regardless of ownership

Included in GDP	Excluded from GDP
Paid childcare services	Unpaid childcare and household work
Newly produced market goods and services	Volunteer services
Government services valued at cost	The resale value of used goods
Imputed rent for owner-occupied homes	Many benefits from free digital services

Note: Unreported market activity is conceptually included in GDP, but it is difficult to observe and may be underestimated

Housing

Included in GDP	Excluded from GDP
New home construction and major renovations	Purchase price of an existing home
Real-estate, legal, and inspection services associated with a sale	A capital gain, or increase in the owner's housing wealth
Rent and the imputed rental value of owner-occupied homes	

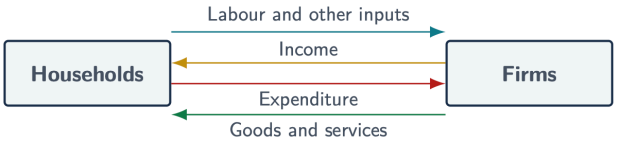

Own house ⟶ Imputed rent ⟶ Net amount ⟶ GDP **Note**: GDP records current housing production and services, not changes in the value of existing property

2.2 Measurement of GDP

Three methods of measuring GDP:

1. **Production method(value-added)**
2. **Income method**
3. **Expenditure method**

The Circular Flow Connects the Three Approaches

$$\boxed{\text{Production} = \text{Income} = \text{Final expenditure}}$$

Info — Production Method

Value-added Method

$$\text{Gross value added} = \text{value of output} - \text{cost of intermediate inputs}$$

- Intermediate inputs are goods and services purchased from other firms and used to produce current output
- Adding the value created at each stage of domestic production measures total value added without counting intermediate inputs more than once.

From valued added to GDP: StatCan adds taxes on products and subtracts subsidies on productws when calculating the published GDP total

Examples:

1. Suppose we have a simple economy:
   - Farmer sells wheat to miller for 80
   - Miller sells flour to baker for 140
   - Baker sells bread to consumer for 220

   We have:

   $$\begin{aligned} \text{Farmer} &: 80 - 0 = 80 \\ \text{Miller} &: 140 - 80 = 60 \\ \text{Baker} &: 220 - 140 = 80 \end{aligned}$$

   $\text{GDP} = 80 + 60 + 80 = 220$

   It is not a coincidence the GDP is same as the price of the bread.
2. Suppose we have another economy measured in thousands of dollars

- Forestry company: sells logs to a CAN sawmill for 300 and uses imported fuel woth 50
- Sawmill: buys logs and imported processing materials worth 80. Sells lumber worth 600 to a CAN funirture producer and exports another 100
- Furniture producer: buys lumber and imported components worth 150. Sells furniture worth 1100 and adds finishd worth 100 to its inventories.

We have

$$\begin{aligned}\text{Forestry company} &: 300 - 50 = 250\\ \text{Sawmill} &: 600 + 100 - 380 = 320\\ \text{Furniture producer} &: 1200 - 600 - 150 = 450\end{aligned}$$

Total GDP $= 1020$

> **Info — Income Method**
>
> - **Compensation of Employees**: wages, salaries, and employer's social contributations
> - **Gross operating surplus**: income generated mainly by incorporated buesiness, before deducting deprectiation
> - **Gross mixed income**: income of unincorporated business, combining returns to the owner's labour and capital
> - **Taxes less subsidides on productions and products**: taxes associated with production and sales, net of subsidies
>
> The formula:
>
> $$\text{Net domestic product} = \text{GDP} - \text{depreciation}$$

Note: The biggest component of the Income method is Compensation of Employees, then it is Gross operating surplus

> **Info — Expenditure method**
>
> C: Household consumption
>
> I: Business fixed, residential, and inventory investment
>
> G: Government purchases of goods and services
>
> $X - M = NX$: Exports minus imports or Net exports
>
> Formula:
>
> $$Y = C + I + G + (X - M) = C + I + G + NX$$

Consumption	**Investments**
Goods(42%) • Durables lasts more than 2 years, volatile	**Buesiness fixed investments** • Equipments

• Semi-durables last less than 2 years • Non-durables do not last, non-volatile	• Structures • Intellectual property products
Services(58%)	**Residential investment** • New housing construction • Major improvements
	Inventory investment The change in firms' stocks of unsold goods(leading indicator)
	Buying a newly issued share provides financing to a firm, but the share is a financial asset rather than newly produced capital.

- Production above sales rises inventories and creates positive inventory investment
- Sales above current production reduce inventories and create negative inventory investment
- Inventory accumulation may be planned or may result from unexpectedly weak sales

Government

Included in G	Excluded in G
Public-school teaching services	Employment Insurance benefits
Medical equipment	Old Age Security payments
Roads and public infrastructure	Student grants
Government employee compensation	Interest on government debt

Note: transfers redistribute purchasing power, do not account for production(GDP)

Import/Exports

- Consumption, investment, and government purchases can include imported goods and services.
- Subtracting imports removes the foreign-produced portion already included in C, I, G
- Exports include Canadian production purchased by buyers abroad

Example:

1. A CAN retailer imports an appliance for $500 and sells it to a household for $650

   $C = 650, M = 500, C - M = 150$

   The remaining $150 represents domestic retail output and equals the retailer's value added in this changes

2.

Transaction	Amount
Household consumption	1,200
Business fixed investment	220
New housing construction	140
Beginning inventories	80
Ending inventories	65
Government purchases	300
Government transfers	90
Exports	190
Imports	200

$Y = C + I + G + (X - M)$

$C = 1200$

$I = 220 + 140 + (65 - 80) = 345$

$G = 300$

$X - M = 190 - 200 = -10$

$\text{GDP} = 1835$, inventory $= 65 - 80 = 15$

2.4 Real and Nominal GDP

📘 **Definition — Real and Nominal GDP**

Nominal GDP values production using prices from the current periods

$$\sum_i P_i Q_i$$

- Nominal GDP can therefore change because quantities change, price change, or both change

Real GDP measures GDP by removing the effects or prices

Nominal GDP	Real GDP
Values production using current price	Adjust for changes in the overall price level
Reflects changes in both quantity and prices	Measures changes in volumes of production

Example:

Item A:
2024 costs 100 $\implies$ 2025 costs 150

Nominal Wage increases by 30%:
2024 : 100 $\implies$ 2025 : 130

You get worse off because purchasing power decreased. Before 100 can buy item A, now you can no longer purchase item A with your wage.

This is the **money illusion**, nominal wage increase $\neq$ purchasing power

📘 **Definition — GDP Implicit Price Index**

It measures changes in the prices of domestically produced final goods and services.

$$\text{GDP price index} = \frac{\text{Nominal GDP}}{\text{Real GDP}} \times 100$$

- It is called **implicit** because it is derived from nominal and real GDP
- In contrast, the CPI measures price changes for a representative basket of gooods and services purchased by consumers
- The GDP price index covers domestically produced final output, including exports. The CPI covers consumer purchases, including imported consumer products.

Example:

	Base Year	Current Year		
Good	Price	Quantity	Price	Quantity
Coffee	3	1000	4	1200
Book	20	100	22	110

Nominal GDP $= 4 \cdot 1200 + 22 \cdot 1100 = 7220$

Real GDP $= 3 \cdot 1200 + 20 \cdot 110 = 5800$

GDP price index: $\frac{7220}{5800} \cdot 100 = 124.48$

Note: Nominal GDP growth $\approx$ Real GDP growth + GDP-price inflation

Chain-weighted GDP

GDP current year at current year prices, GDP current year at previous year prices

GDP previous year at current year prices, GDP previous year at previous year prices

$\text{GDP} = \sqrt{\text{Growth rate between last year prices} \cdot \text{Growth rate based on this year prices}}$

2.3 GDP Growth

📘 **Definition — Growth Over Different Time Horizon**

Y_t is GDP in the current period, while Y_{t-k} is GDP k periods earlier in pervious years.

$k = 1$ to calculate month-to-month or quarter-quarter growth

$k = 4$ for quarterly data and $k = 12$ for monthly data

$$g_t = \left(\frac{Y_t - Y_{t-k}}{Y_{t-k}}\right) \cdot 100 = \left(\frac{Y_t}{T_{t-k}} - 1\right) \cdot 100$$

📘 **Definition — Annualized Growth Rate**

$$A_G = \left[\left(\frac{\text{GDP}_t}{\text{GDP}_{t-1}} \right)^m - 1 \right] \cdot 100$$

$m =$ months have passed

It takes the assumption of the growth rate of the economy is constant

It is more volatile compared to YoY growth rate

Example:

We have a share that is 200 in Jan and 220 in Sept,

The $Y_{TD} = \left(\left[\frac{220}{200} \right]^9 - 1 \right) \cdot 100 \approx 135.8\%$

2.4 GDP per Capita

📘 **Definition — GDP per Capita**

$$\text{Real GDP per Capita} = \frac{\text{Real GDP}}{\text{Population}}$$

Output per worker = how much each worker produces given technology + resources

Productivity:

- Technology, R&D investment
  - 2% in Canadian
  - 4% in US
- Market Structures
  - Tax rate
  - Barrier to trade

Regressive taxes: GST tax

Progressive taxes: Income tax

2.5 Growth National Income

📘 **Definition — Gross National Income/(Gross Naitonal Product)**

$$\text{GDP} + \text{Income from domestic's abroad workers} - \text{Income from foreign worker}$$

Examples:

1. Ireland: GDP $>$ GNI:
   - 0 Coporate tax attracts many foreign companies putting as headquarters
2. Philippines: GDP $<$ GNI:
   - Many Philippinos are foreign workers and send back their money.

Hidden Production

The unreported, informal, and illegal activities should be included in GDP but are hard to record so often not included.

Once unreported markets become legal, it will boosts GDP. Adjustments will be done to inculde previously illegal and assume they were legal.

Note:

GDP per capita measures WELL:

- Standardized production
- Adjust total output for Population
- Supports comparison across time
- Correlates with many material and health outcomes.

It does NOT measure:

- Distribution
- Leisure and unpaid work
- Environmental damage.
- Health, Security, Freedom

2.6 GDP Comparison

Exchange Rate complicates GDP Compariosn

- Countries report GDP in their own currencies, so international comparisons require converting GDP into a common currency.
- One approach is to convert each country's GDP into U.S. dollars using the market exchange rate.
- However, exchange rates can change sharply even when the amount a country produces changes very little.
- GDP converted at market exchange rates can therefore make an economy appear larger or smaller without a corresponding change in its production.

Purchasing Power Parity

Instead of market exchange rate, we use purchasing power parity.

Example:

Basket of oranges costs 10 CAD or 7USD, then it will be 10:7 for the purchasing power parity
